## Lecture 1: 1/9/2024

A graph is a pair  $(V, E)$  where  $V$  is a set of vertices and  $E$  is a set of unordered pairs of elements of  $V$  called edges. For  $u, v \in V$ , we say  $u$  and  $v$  are adjacent if  $\{u, v\} \in E$ .

For example:  $G = (\{1, 2, 3\}, \{\{1, 2\}, \{2, 3\}\})$

A directed graph (a.k.a a digraph) is a pair  $(V, E)$  where  $V$  is a set of vertices and  $E$  is a set of ordered pairs of elements of  $V$ .

For example:  $G = (\{1, 2, 3\}, \{(1, 2), (2, 3)\})$

A multigraph is a pair  $(V, E)$  where  $V$  is a set of vertices and  $E$  is a multiset of unordered pairs of elements of  $V$ .

For example:  $G = (\{1, 2, 3\}, \{\{1, 2\}, \{2, 3\}, \{2, 3\}\})$

A pseudograph is like a graph and multigraph except that the pairs in  $E$  are multisets. Essentially, an element  $\{a, a\}$  can belong to  $E$  in a pseudograph. This type of edge is called a loop.

For example:  $G = (\{1, 2, 3\}, \{\{1, 2\}, \{2, 3\}, \{3, 3\}\})$

If  $G = (V, E)$  and  $v \in V$ , the neighborhood of  $v$  is  $N_G(v) = \{w \in V \mid \{v, w\} \in E\}$ .

The degree of  $v$  is  $d_G(v) = |N_G(v)|$ . Or in other words,  $v$ 's degree is equal to the number of edges connecting to  $v$ .

---

The Handshaking lemma states that for any graph  $(V, E)$ :

$$\sum_{v \in V} d_G(v) = 2|E|$$

The reason for this is that each edge increments the degrees of exactly two vertices. So the above sum counts every edge twice.

Lemma: Every graph has an even number of vertices with odd degrees.

Proof: We can split the vertices of any graph into two categories: those with odd degrees, and those with even degrees.

Now recall that an even number plus an even number always equals an even number, as does an odd number plus an odd number. However, an odd number plus an even number equals an odd number. Based on this fact, we can guarantee that the sum of even degrees in any graph is even. And since the sum of even degrees plus the sum of odd degrees must be even as it equals  $2|E|$  by the Handshaking lemma, we thus know that the sum of odd degrees must be even. Hence, it must be the case that there are an even number of vertices with odd degree because otherwise the sum of their degrees won't be even.

A graph is called  $r$ -regular if all of its vertices have degree  $r$ .

Note that the number of edges in any  $n$ -vertex  $r$ -regular graph is  $\frac{rn}{2}$ .

An  $r$ -dimensional cube graph, denoted as  $Q_r$ , is a graph such that  $V(Q_r)$ , the set of vertices in  $Q_r$ , is equal to the set of binary strings of length  $r$ ; and  $E(Q_r)$ , the set of edges in  $Q_r$ , is equal to the set of pairs of binary strings which differ in one position.
